

# RECENT DEVELOPMENTS AT THE CDDIS

Since 1982, the Crustal Dynamics Data Information System (CDDIS) has supported the archive and distribution of geodetic data products acquired by NASA as well as national and international programs. These data include GNSS (Global Navigation Satellite System), SLR (Satellite and Lunar Laser Ranging), VLBI (Very Long Baseline Interferometry) and DORIS (Doppler Orbitography and Radiolocation Integrated by Satellite). The CDDIS data system and its archive have become increasingly important to many national and international science communities, particularly several of the operational services within the International Association of Geodesy (IAG) and its project the Global Geodetic Observing System (GGOS), including the International DORIS Service (IDS), the International GNSS Service (IGS), the International Laser Ranging Service (ILRS), the International VLBI Service for Geodesy and Astrometry (IVS), and the International Earth Rotation Service (IERS). The CDDIS has recently implemented a new, distributed hardware architecture. This poster will include background information about the system and its user communities, archive contents, available metadata, new system architecture, and future plans.

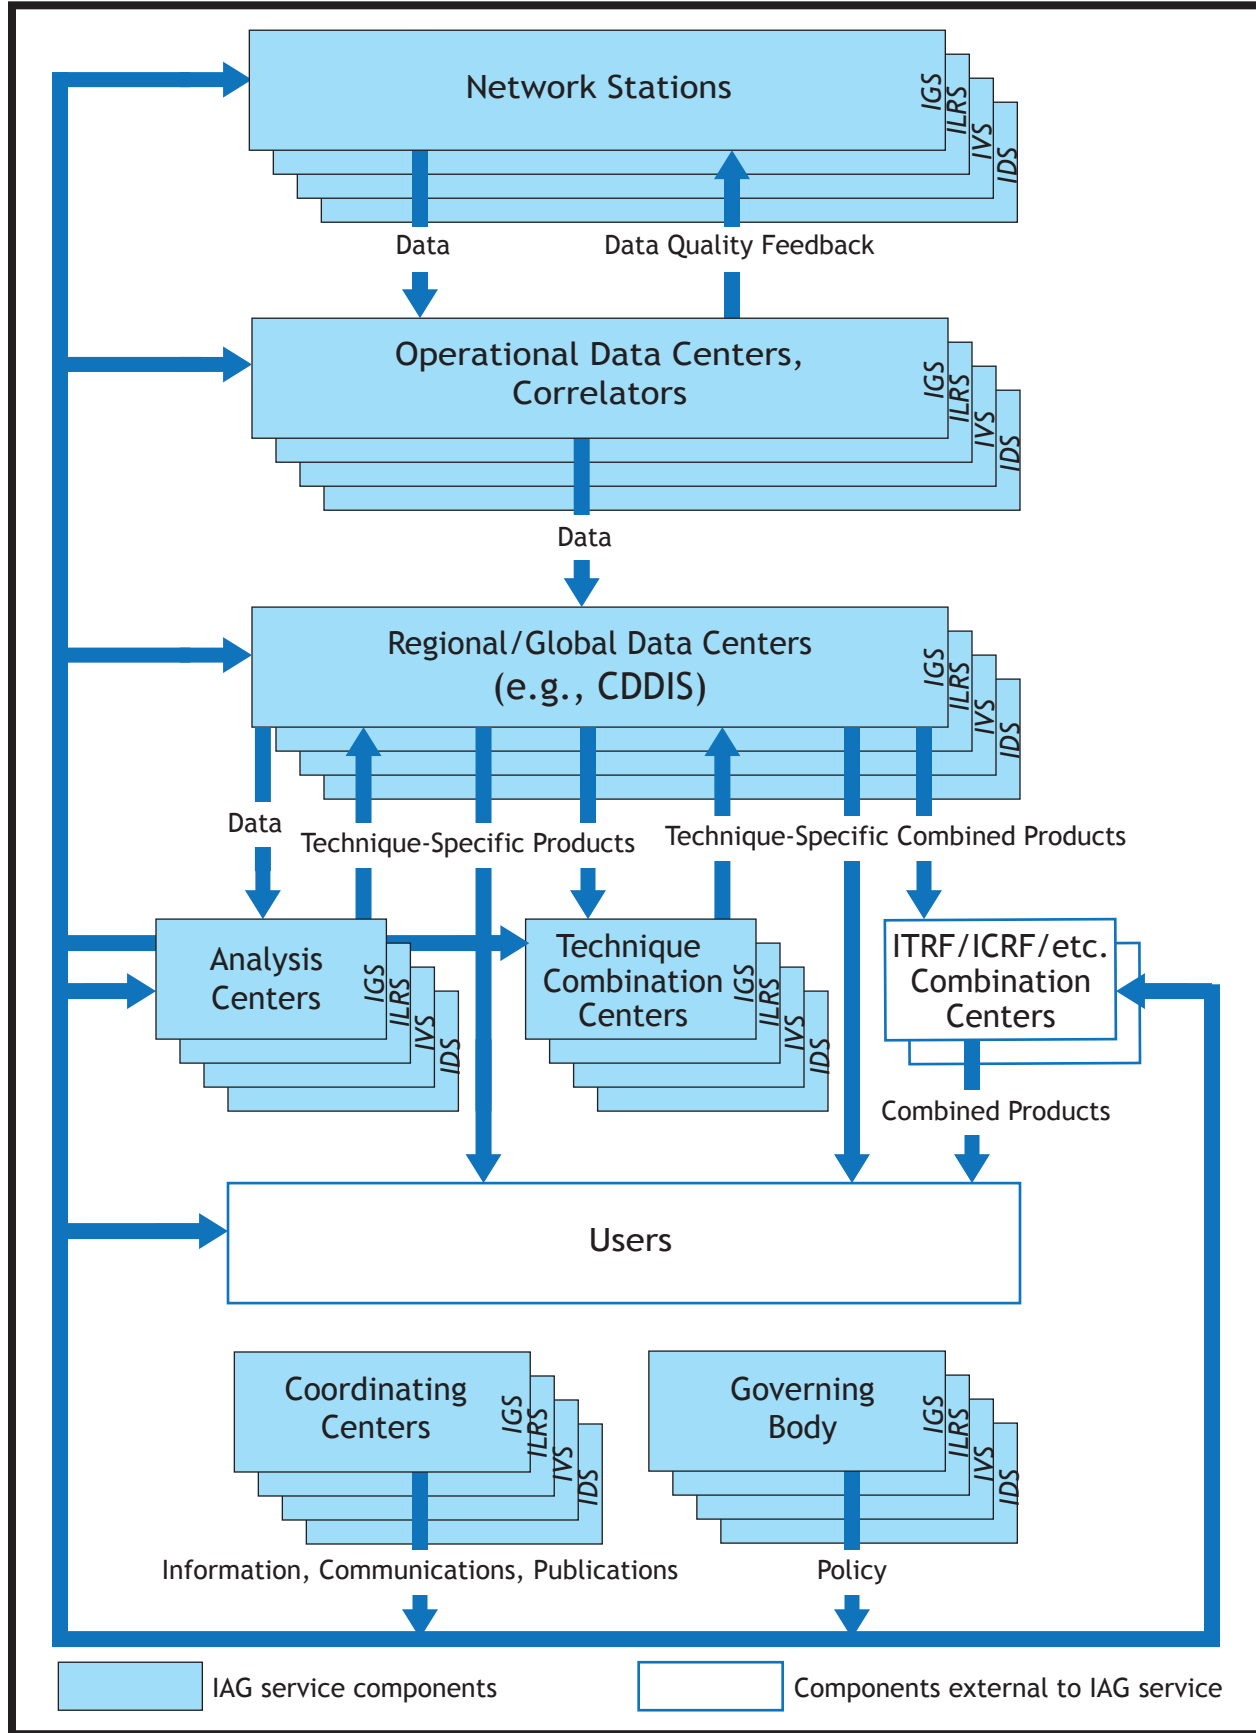

## DATA FLOW IN SUPPORT OF IAG SERVICES

Today's global network of geodetic observing sites includes 421 GNSS receivers, 40 laser ranging sites, 44 VLBI stations, and 56 DORIS sites. The CDDIS provides data from these sites and higher-level products derived from these data.

An essential element to the operation of all of the IAG's international scientific services (the IGS, ILRS, IVS, and IDS) is their information system and archive components. These archives are the central source of data for the services' analysis communities as well as those products generated by the analysis centers for use by a broader user community. The CDDIS serves as the single data center resource from which the data from all these networks (IGS, ILRS, IVS, and IDS), and the resulting products derived from their data, may be accessed.

The IGS, as well as the ILRS, IVS, and IDS, makes use of a similar, distributed data flow structure for the transmission of information, data, and derived products from the observing stations to the user community. The structure for the services can be divided into the following components: Network Stations, Data Centers Analysis Centers, Analysis Center Coordinators, a Coordinating Center, and a Governing Body. Participants in these service activities collaborate at all levels to ensure consistency and timely delivery of data and products. GNSS (and laser ranging, VLBI, and DORIS) data are transmitted through the various levels shown in the figure to ultimately arrive at the analysis centers, combination centers, and general user community.

## CDDIS REPORTING

IGS Tracking Network Status for 10-May-10 100510 10130										GPS Week 1583 Day 2										As of date: May 17 2010 10/27:21

The breakdown of the contents of the CDDIS archive by type in 2010. The majority of the online storage is devoted to the archive of GNSS data. The CDDIS GNSS archive consists of 19 years of daily, 30-second files (420 sites in 2010), 3 years hourly, 30-second data (280 sites in 2010), 10 years of high-rate 1-second data (140 sites in 2010), and 18 years of GNSS product files.

Profile of users retrieving files (based on volume) from the CDDIS archive in 2008.

The breakdown of CDDIS archive downloads by volume for 2009 categorized by data/product type. A further breakdown by data format and processing level is shown for GNSS-related downloads.

Carey Noll, NASA GSFC  
Maurice Dube, NASA GSFC/SSAI  
Patrick Michael, NASA GSFC/Catholic University

## CDDIS ARCHIVE PROCESSING

The update process for the CDDIS archive process can be divided into several structural components allowing for efficient and secure processing: deposit, operations, download, and archive support.

DEPOSIT: Suppliers of content for the archive (e.g., network tracking data from operational centers, products from analysis centers, etc.) transfer their data and product files to the CDDIS deposit or "incoming" disk location using ftp. These incoming accounts have limited privileges allowing users to only deposit files. In a few cases, the CDDIS will retrieve files for the archive from data/product sources. All suppliers access a server dedicated to receipt of incoming files.

OPERATIONS: All processing of incoming files takes place in the CDDIS operations area, which is accessible to internal users only. Software scans the deposit directories on pre-determined schedules dependent upon the type of incoming files and copies the files to temporary locations where their contents are validated for readability and integrity (format and content) and metadata are extracted and loaded into a relational database. Valid files are moved to the CDDIS archive.

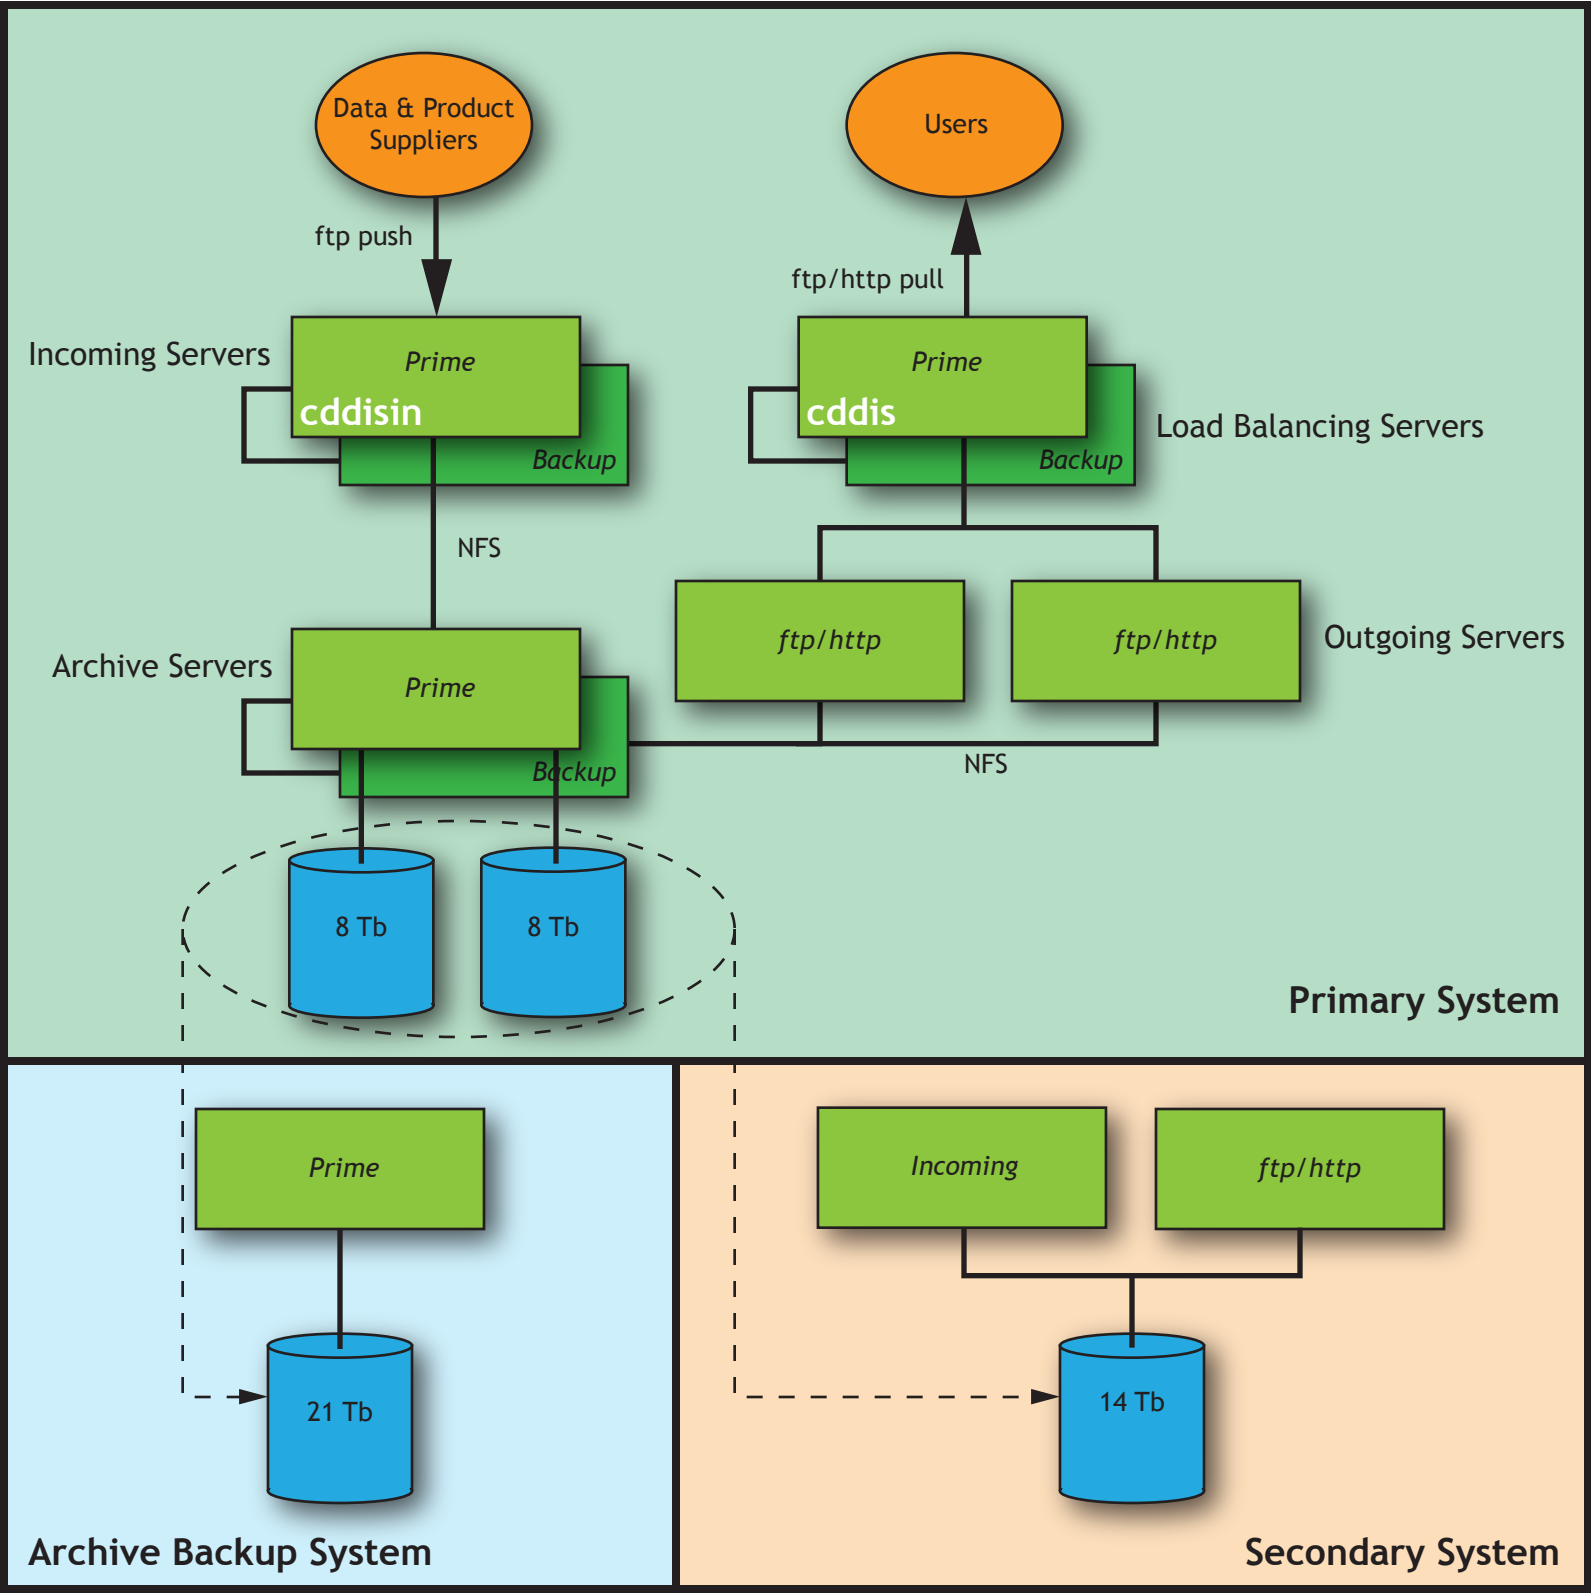

DOWNLOAD: The CDDIS public archive is openly accessible to the scientific community through anonymous ftp and the web (future enhancements will permit http access to the CDDIS archive). It is the repository for all valid files provided by the operational/regional/global data centers, analysis centers, and analysis center coordinators. The structure of the archive follows conventions established within the services and thus is data type (i.e., GNSS, SLR, VLBI, or DORIS) dependent. All users access a separate computer system dedicated to serving files from the archive's disk farm.

ARCHIVE SUPPORT: A final portion of the CDDIS archive update process is devoted to utilizing extracted metadata to maintain supporting information, particularly files summarizing the contents of the download area, statistics on the timeliness of the incoming files, etc.

## NEW CDDIS COMPUTER ENVIRONMENT

On June 21, 2010 the CDDIS transitioned operations to a new distributed server environment. This new configuration allows for efficient and timely processing of incoming files as well as enhanced system security by separating user/archive functions. Distinct servers handle incoming data and product files (server [cddisin.gsfc.nasa.gov](http://cddisin.gsfc.nasa.gov)), outgoing ftp and http requests (server [cddis.gsfc.nasa.gov](http://cddis.gsfc.nasa.gov)), and archive operations to the RAID storage. Servers handle load balancing on incoming queries for files to host [cddis.gsfc.nasa.gov](http://cddis.gsfc.nasa.gov). The archive server manages the RAID storage and its connections to the incoming and outgoing servers. Each server has a "hot spare" which can take over operations should a failure occur with the prime server. Additional RAID storage has been installed to bring the total available storage for the CDDIS archive to nearly 16 Tbytes, plus additional internal storage for processing and database applications. The CDDIS archive increases in size by approximately 1 Tbyte/year; the existing storage will accommodate the archive requirements for the near future. The CDDIS computer system also includes a secondary server for daily backup of the archive. Furthermore, two additional servers and RAID arrays will be set up in the next few months at another GSFC location to provide a complete backup server environment should access to the primary systems be disabled.

In addition to computer hardware changes, the CDDIS replaced its internal database management software (Oracle) with MySQL. This change required modification to database schemas, supporting software, and report queries.

## FUTURE DEVELOPMENTS

METADATA UPDATES: Metadata can be thought of as "data about data". They describe what, where, when, and by whom a set of data or products were collected. Metadata are used to manage the data archive and aid in access to this archive.

Today, CDDIS software extracts metadata as part of its data validation and ingest process. The fields and format of these metadata are dependent upon data type and processing level. However, to support integration of information about IAG service data and product holdings into the GGOS portal, the CDDIS staff has begun development of a new metadata model to be used for all types of data and products archived in the system. The model will be based upon internationally-recognized metadata standards in cooperation with GGOS and the EOSDIS Clearing House (ECHO). Some of the parameters to be addressed in the new model include descriptions at various levels: collection (e.g., laser ranging normal points, IGS final orbits, etc.) granule (e.g., daily RINEX observation data for GODE on day 10152, IGS final clock solution for day 3 of week 1582, etc.) ancillary (e.g., station code GODE refers to a site at Greenbelt, MD, etc.).

Several standards have been developed for metadata. GGOS will base its metadata model on ISO 19511 and will provide core metadata information for all geodetic data sets from the contributing IAG services. Therefore, these services will need to provide metadata, through their data centers, following this model so that their data are discoverable in the GGOS portal. The model can be extended to include other metadata required by the individual services and or data centers.

USER INTERFACE ENHANCEMENTS: One area of improvement for the CDDIS is in discovery of the system's contents for both new users and for the existing user base. The average user of the CDDIS today accesses the contents of the archive through anonymous ftp by means of automated scripts. Analysts can use this method for data transfer because they are familiar with the structure of the CDDIS and thus know what files they require, their availability schedule, and where to find them within the online structure. However, new users of the CDDIS, both those familiar with space geodesy techniques as well as new research communities, would prefer a browsing interface to the archive contents. Therefore, the CDDIS will undertake the design of a web interface based search tool that queries the CDDIS metadata. Users will have the ability to specify search criteria based on temporal, spatial, target, site designation, and/or observation parameter in order to identify data and products of interest for download. Results of these queries will include a listing of sites (or other metadata) or data holdings satisfying the user input specifications. Such a user interface will also aid CDDIS staff in managing the contents of the archive.

OTHER UPDATES UNDER CONSIDERATION: Data centers, including the CDDIS, fight a continuous battle to manage an ever-increasing archive in an efficient manner. During our transition to the new server environment, the CDDIS staff realized that the large number of nested directories used in archiving some data sets, e.g., high-rate GNSS data, is not efficient for storage or access. However, there is a need to balance efficiency with user requirements. To that end, the CDDIS will study ways to simplify storage of selected data sets, such as the high-rate GNSS data. As an example, a day's worth of GNSS high-rate data could be consolidated by packaging all files into a single site's tar file, (e.g., `gode1150_10d.tar.gz` contains all high-rate observation data from GODE for day 10115). Users can then download a single file/day to retrieve all high-rate data for sites of interest. Similar consolidation could be performed on other data sets as is practical. Any changes would be implemented in the historic data directories (e.g., prior to 2009); operational changes would be coordinate with IGS Infrastructure Committee and Data Center Working Group.

The current compression scheme used in the IGS (and other IAG service infrastructures), UNIX compress, is inefficient and out of date. The IGS Data Center Working Group (DCWG) is currently reviewing options for implementing alternate compression software. Any change to compression software would involve not only the data centers but other components including the analysis centers, user community in general, and receiver manufacturers, many of whom implement compression in their firmware. However, it is reasonable to allow data centers to alter compression used in older data sets to realize a more efficient data storage. Currently, gzip and bzip2 are options under investigation to replace UNIX compress.

The CDDIS staff will look for feedback prior to implementing any significant changes such as these to the archive.
